Abstract

This paper is a case study in proof mining applied to non-effective proofs in nonlinear functional anlysis. More specifically, we are concerned with the fixed point theory of nonexpansive selfmappings f of convex sets C in normed spaces. We study the Krasnoselski iteration as well as more general so-called Krasnoselski-Mann iterations. These iterations converge to fixed points of f only under special compactness conditions and even for uniformly convex spaces the rate of convergence is in general not computable in f (which is related to the non-uniqueness of fixed points). However, the iterations yield approximate fixed points of arbitrary quality for general normed spaces and bounded C (asymptotic regularity).

In this paper we apply general proof theoretic results obtained in previous papers to non-effective proofs of this regularity and extract uniform explicit bounds on the rate of the asymptotic regularity. We start off with the classical case of uniformly convex spaces treated already by Krasnoselski and show how a logically motivated modification allows to obtain an improved bound.

1

Already the analysis of the original proof (from 1955) yields an elementary proof for a result which was obtained only in 1990 with the use of the deep Browder-Göhde-Kirk fixed point theorem. The improved bound from the modified proof gives applied to various special spaces results which previously had been obtained only by ad hoc calculations and which in some case are known to be optimal.

The main section of the paper deals with the general case of arbitrary normed spaces and yields new results including a quantitative analysis of a theorem due to Borwein, Reich and Shafrir (1992) on the asymptotic behaviour of the general Krasnoselski-Mann iteration in arbitrary normed spaces even for unbounded sets C. Besides providing explicit bounds we also get new qualitative results concerning the independence of the rate of convergence of the norm of that iteration from various input data. In the special case of bounded convex sets, where by well-known results of Ishikawa, Edelstein/O'Brian and Goebel/Kirk the norm of the iteration converges to zero, we obtain uniform bounds which do not depend on the starting point of the iteration and the nonexpansive function and the normed space X and, in fact, only depend on the error ε, an upper bound on the diameter of C and some very general information on the sequence of scalars λ_k used in the iteration. Even non-effectively only the existence of bounds satisfying weaker uniformity conditions was known before except for the special situation, where $\lambda_k := \lambda$ is constant. For the unbounded case, no quantitative information was known so far.

1 General introduction

This paper is another case study in the project of 'proof mining'[1] in analysis by which we mean the logical analysis of mathematical proofs (typically using non-effective analytical tools) with the aim of extracting new numerically relevant information (e.g. effective uniform bounds or algorithms etc.) hidden in the proofs.[2]

Let us discuss in more detail what kind of numerical information we are aiming at. Many problems in numerical (functional) analysis are concerned with the construction of solutions x of certain equations $A(x)$, where x is element of some Polish space (typically with additional structure) and $A(x)$ can be written as $F(x) = 0$ for some

---

[1] The term 'proof mining' (instead of G. Kreisel's 'unwinding of proofs') for the activity of extracting additional information hidden in given proofs using proof theoretic tools was suggested to the author by Professor Dana Scott.

[2] For a different case study in analysis in the context of best approximation theory see [21],[22]. For other kinds of logical analyses of specific proofs see [32] and [35].

continuous function $F : X \rightarrow \mathbb{R}$ (usually A, and hence F, will depend on certain parameters a which again belong to Polish spaces). The construction of a solution for A quite often involves two distinct steps:

1) Approximate solutions (also called 'ε-solutions') $x_n \in X$ satisfying $A_{\frac{1}{n}}(x_n)$ with

$$A_\varepsilon(x) :\equiv (|F(x)| < \varepsilon)$$

   are constructed (uniformly in the parameters of A).

2) One shows, using e.g. compactness arguments, that either $(x_n)_{n \in \mathbb{N}}$ itself or some subsequence converges to a solution of $A(x)$.

It is the non-effectivity of the second step which in many cases prevents one from being able to compute a solution $\widehat{x}$ of A effectively within a prescribed error $\frac{1}{k}$, i.e. to compute a function $n(k)$ such that $d_X(x_{n(k)}, \widehat{x}) < \frac{1}{k}$. Even when $X := K$ is compact and $\widehat{x}$ is uniquely determined, so that (x_n) itself converges to $\widehat{x}$, explicit a-priori bounds (in particular not depending on $\widehat{x}$ itself) on the rate of convergence of that sequence are often not provided in numerical analysis (due to the ineffectivity of the proof of the uniqueness of $\widehat{x}$).[3]

In several papers we have shown how proof theoretic techniques can be applied to extract certain quantitative information (so-called uniform moduli of uniqueness which generalize the concept of strong unicity as used e.g. in Chebycheff approximation theory) even from highly non-constructive uniqueness proofs and how effective rates of convergence can be obtained using this information (see [25] for an introduction to this and [21],[22],[23] for concrete applications to approximation theory).

In this paper we are concerned with applications to the first of the two steps mentioned above in situations where an effective solution of 2) is not possible (mainly due to the lack of uniqueness).

These applications to 1) fall under (an extension of) the general logical scheme as our previous applications to 2) where an instance of. In a series of papers ([23],[24],[25],[27] among others) we have developed general meta-theorems which guarantee the extractability of uniform bounds from proofs which are allowed to make use of substantial parts of analysis. In particular, we specified situations where (due to the fact that only weak forms of induction are used) exponential and even polynomial bounds are guaranteed. Furthermore, these results show that many lemmas used in such proofs do not need to be analysed (since they do not contribute to

---

[3]See also [31] for an interesting discussion of this and related points.

the bound) because of their logical form. The proofs of these meta-theorems actually provide an extraction algorithm (based on certain proof-theoretic transformations of the specific proof to be analyzed). So applied to a given proof p in analysis we get another proof p^* which provides more numerical information. When this transformation is carried out explicitly we obtain a new ordinary mathematical proof of a stronger statement which no longer relies on any logical tools at all. Of course, the general proof-theoretic algorithm will usually be used only as a guideline but not followed step by step in the actual construction of p^* (unless this is necessary).

The special case of our general meta-theorems which is relevant for the present paper has the following form:

Let X be a Polish space, K a compact metric space and A_1 a purely existential property. If a theorem of the form

$$(*) \ \forall n \in \mathbb{N} \forall x \in X \forall y \in K \exists m \in \mathbb{N} A_1(n, x, y, m)$$

has been proved in certain formal systems $\mathcal{T}$ for (fragments of) analysis, then one can extract a computable uniform bound $\Phi(n, x)^4$ for $\exists m$, i.e.

$$\forall n \in \mathbb{N} \forall x \in X \forall y \in K \exists m \leq \Phi(n, x) A_1(n, x, y, m).$$

An important feature of the bound $\Phi(n, x)$ is that it does not depend on $y \in K$. Typically, $\exists m A_1$ is monotone in m so that the bound $\Phi(n, x)$ actually realizes the quantifier. In [25] we have specified a system **PBA** of polynomially bounded analysis which guarantees that $\Phi(n, x)$ will be a polynomial. If we add the exponential function to **PBA** we obtain a system **EBA** which guarantees that Φ uses at most a finite iteration of exp (so if exp is not iterated at all the bound will be exponential in n relative to x). Whereas for our first application in the present paper (theorem 3.9 below) this result for **PBA** is already sufficient for providing the general logical framework, our analysis of a proof from [4] carried out in theorem 4.5 needs an extended version due to the use of a principle used in that proof which is not available in **PBA** or **EBA**. Whereas these systems contain quite some parts of non-constructive analysis, principles based on sequential compactness are not included. The significant and highly non-trivial impact of such principles for the extraction of bounds has been determined completely in [27] and [28]. We only discuss the results for the particular simple case of the principle

$$\mathrm{PCM}(a_k) :\equiv [\forall n(0 \leq a_{n+1} \leq a_n) \rightarrow \exists a \in \mathbb{R}_+ (\lim_{n \to \infty} a_n = a)]$$

---

[4]This bound (as well as the logical form of A_1) will in general depend on the specific representation of $x \in X$ used in $\mathcal{T}$.

of convergence for bounded monotone sequences $(a_n)_{n \in \mathbb{N}}$ of reals, as it is this principle which is used in the proof from [4] we are going to analyse. In systems like **PBA**, real numbers are represented as Cauchy sequences of rational numbers with fixed rate of convergence. Because of this representation $\text{PCM}(a_n)$ is a fairly strong principle equivalent to

$$(+) \; \forall n(0 \leq a_{n+1} \leq a_n) \rightarrow \exists f : \mathbb{N} \rightarrow \mathbb{N} \forall k, m(m \geq f(k) \rightarrow a_{f(k)} - a_m \leq \frac{1}{k+1}).$$

Because of the existence of the 'Cauchy modulus f', '$\forall (a)_n \; \text{PCM}(a_n)$' is equivalent to the principle of so-called arithmetical comprehension which potentially creates bounds of huge complexity when added to systems like **PBA**, **EBA** (see [28]). What we showed in [27] is, that things are quite different when $\text{PCM}(a_n)$ is only applied to sequences (a_n) in a given proof of a theorem $(*)$ which can be explicitly defined in terms of the parameters n, x, y of $(*)$. Then, relative to **PBA** and **EBA**, the use of $\text{PCM}(a_n)$ can be reduced to its arithmetical version[5]

$$\text{PCM}_{ar}(a_n) :\equiv \left[\forall n(0 \leq a_{n+1} \leq a_n) \rightarrow \forall k \exists n \forall m(m \geq n \rightarrow a_n - a_m \leq \frac{1}{k+1}) \right].$$

By further proof theoretic considerations, the use of PCM_{ar} can even be reduced to that of its so-called 'no-counterexample interpretation' (or 'Herbrand normal form')

$$\text{PCM}_{ar}^H(a_n) :\equiv \left[\forall n(0 \leq a_{n+1} \leq a_n) \rightarrow \forall k, g \exists n(g(n) \geq n \rightarrow a_n - a_{g(n)} \leq \frac{1}{k+1}) \right].$$

The computational significance of this reduction is, that in contrast to the quantifier dependency '$\forall k \exists n$' in PCM_{ar}, which in general has no computable bound, the quantifier '$\exists n$' in PCM_{ar}^H can be bounded (uniformly in k, g and an upper bound $N \in \mathbb{N}$ of a_0) by $\widehat{\Psi}(k, g, N) := \max_{i \leq (k+1)N} \Psi(i, g)$, where $\Psi(k, g)$ is the k-times iteration of g applied to 0, i.e.

$$\Psi(0, g) := 0, \; \Psi(k+1, g) := g(\Psi(k, g))$$

(see [27] for details on all this). We like to stress, that this quantitative bound for $\text{PCM}_{ar}^H(a_n)$ only depends on (a_n) via an upper bound $N \geq a_0$ whereas a bound for

---

[5]Because of $(+)$, $\text{PCM}(a_n)$ essentially is the so-called Skolem normal form of $\text{PCM}_{ar}(a_n)$. In general it is NOT possible (in a context like **PBA** or **EBA**) to reduce the use of the Skolem normal form of an arithmetical principle A to A itself. The fact that this IS possible for PCM_{ar} makes profound use of the fact that this principle satisfies a strong monotonicity property, see [26].

$\exists n$ in $\mathrm{PCM}_{ar}(a_n)$ of course has to depend on (a_n). So the reduction from $\mathrm{PCM}_{ar}(a_n)$ to $\mathrm{PCM}_{ar}^H(a_n)$ also provides an important independence from (a_n) which will play a crucial role in our proof of corollaries 4.6 and 4.8 below.

We have seen that the use of $\mathrm{PCM}(a_n)$ for definable (a_n) contributes to the bound Φ by $\widehat{\Psi}$. By finite iteration, Ψ (and hence $\widehat{\Psi}$) is able to produce arbitrary primitive recursive growth rates. However, in practice it will usually only be applied to some fixed functions g which can explicitly defined in terms of the parameters of the problem. It is the construction of these functions which plays a crucial role in the process of proof mining. This fact is clearly reflected in the bounds we obtain in theorem 4.5 and corollary 4.6 below (see the definition of $\widehat{\alpha}$ in these results).[6]

We have discussed the logical background of the results in the present paper in some detail in order to convince the reader, that these results are just special instances of a general scheme for proof mining. Once one is familiar with this scheme, one can almost mechanically produce improvements of existence theorems in analysis of the kind we illustrate here using examples from fixed point theory.

2 Applications to the fixed point theory of non-expansive mappings

The examples which we will treat in this paper are taken from the fixed point theory of nonexpansive mappings $f : C \to C$, for certain sets C in normed spaces X. The well-known Banach fixed point theorem tells us that contractive mappings f always have a unique fixed point if X is complete and C is closed and that the sequence $x_{k+1} := f(x_k)$ starting from any $x_0 \in C$ effectively converges to that fixed point. For nonexpansive functions f (i.e. functions which are Lipschitz continuous with Lipschitz constant $\lambda = 1$), in general fixed points only exist if C is closed convex and bounded (by the Browder-Göhde-Kirk fixed point theorem, see theorem 3.3 below). If X is a uniformly convex Banach space, $C \subset X$ is closed convex and bounded and $f(C)$ is a compact subset of C, then a fixed point of f can be approximated by the

---

[6]In the concrete application in this paper it is mainly the reduction from PCM_{ar} to PCM_{ar}^H which plays a significant role in the proof mining. The (in general much more complicated) reduction from PCM to PCM_{ar} is almost straightforward. However, we expect that this will be different for other examples. In any case, we believe that the fact that our applications to concrete proofs reflect crucial steps of the general proof-theoretic reduction and are instances of a general meta-theorem (which at least under an additional compactness assumption predicts the type of results we obtain), makes it justified to call them genuine applications of logic in the sense discussed in [10].

following Krasnoselski iteration (see theorem 3.4 below)[7]

$$x_{k+1} := \frac{1}{2}(x_k + f(x_k)), \ x_0 \in C \text{ arbitrary.}$$

However, the situation still is quite different from the Banach fixed point theorem since

1) f may have several fixed points,

2) a fact closely related to the non-uniquenes of the fixed point is, that the rate of convergence of the Krasnoselski iteration to its limit is not computable uniformly in f and x_0 (see [29]).

So the Krasnoselski iteration does not provide an algorithm for the computation of a fixed point of f (with prescribed precision) but it can be used to find effectively approximate fixed points. Since (x_k) converges to some fixed point of f and f is continuous it is clear that for a sufficiently large n on, x_m $(m \geq n)$ will be an approximate fixed point:

$$(*)\forall \varepsilon > 0 \exists n \in \mathbb{N} \forall m \geq n(\|x_m - f(x_m)\| < \varepsilon).$$

Because of the simple monotonicity property (see lemma 3.8 below)

$$\|x_{m+1} - f(x_{m+1})\| \leq \|x_m - f(x_m)\|$$

the formula

$$\forall m \geq n(\|x_m - f(x_m)\| < \varepsilon)$$

is equivalent to

$$\|x_n - f(x_n)\| < \varepsilon,$$

which (given a representation of real numbers as Cauchy sequences of rational numbers with fixed rate of convergence) is $\in \Sigma_1^0$. That is why we are able to extract an algorithm for n in $(*)$ uniformly in x_0 and f (if X, C have a computable representation).

Let us assume for the moment that $C := K$ itself is compact. Then the standard proof (as given in e.g. [3]) of the Krasnoselski fixed point theorem (more precisely of its consequence $(*)$ above) directly fits into the general extraction scheme discussed

---

[7]Due to a much more general result from [16], which we will discuss below, the assumption of X being uniformly convex actually is superfluous.

above. Besides basic arithmetical reasoning only the existence of a fixed point $y \in K$ of f (which follows from the Schauder fixed point theorem) is used to show $(*)$. Since the statement

$$(a) \; \exists y \in K(\|f(y) - y\| = 0)$$

has the logical form of those assumptions which do not contribute to the growth of extractable bounds and which furthermore can be reduced to their ε-weakening

$$(b) \; \forall \varepsilon > 0 \exists y \in K(\|f(y) - y\| < \varepsilon)$$

and since furthermore the starting point $x_0 \in K$ belongs to a compact set and the set of all nonexpansive mapping $f : K \to K$ is also compact, we know a-priori that the extractability of a uniform bound (of low complexity) for n in $(*)$ which does not depend on x_0 or f (but only on ε and a modulus of uniform convexity) is guaranteed whose verification only uses (b). The actual extraction shows that instead of the compactness only the boundedness of K is needed. This is even true for the reduction of (a) to (b) which allows furthermore to remove the assumption on K being closed (and X being complete), since the existence of approximate fixed points (but not of fixed points) can be shown without these assumptions. This, of course, is an a-posteriori information which was not guaranteed by a general logical result. Nevertheless, the a-priori information provided for the special case with K being compact prompted the search for such uniform bounds. As a result we get for an arbitrary convex bounded subset $C \subset X$ a uniform bound for $(*)$ depending only on ε, a modulus of uniform convexity η of X and an upper bound for the diameter of C. The bound itself is not new: for the special compact case it is essentially already contained in Krasnoselski's original paper ([30]) and was proved for the case of closed bounded convex sets in [18] using the deep Browder-Göhde-Kirk fixed point theorem. We nevertheless carry out the analysis because it shows two phenomena: 1) the possibility of replacing the existence of fixed points by the existence of ε-fixed points which allows to give a complete elementary verification of the bound (without assuming X complete or C being closed). 2) There is a logical modification of the proof from [3] which makes use of the above mentioned no-counterexample interpretation PCM_{ar}^{H} of PCM_{ar} and allows to make use of a certain multiplicative property many moduli η satisfy, by which we obtain (for such moduli) a numerically better result. As a special instance of this we get a bound which is polynomially in ε of degree p for the spaces L_p with $p \geq 2$ (a result which (for this special case only) first was obtained in 1990 in [18] by an ad hoc calculation). For $X := \mathbb{R}, C := [0, 1]$ we even get a linear bound (see also [18], p.192).

What is more interesting is that the authors conjecture in that very paper that 'it

seems unlikely' ([18]), p. 191) that such bounds could easily be obtained in more general situations where X is not required to be uniformly convex. More specifically, in [12](p. 101) it is considered to be 'unlikely' that bounds which only depend on C via an upper bound for the diameter of C exist at all in this general case. It is exactly this general situation which we study in the final and main section of the paper. As a special corollary of a more general result we obtain that in contrast to this conjecture in [12] such uniform bounds not only exist (even for more general so-called Mann iterations, see corollary 4.8) but can be easily described (see corollaries 4.10 and 4.6 below).[8]

Let us discuss this in more detail. We consider strong generalizations of Krasnoselski's result due to [16],[8],[11] and [4]. In [16] it is shown that Krasnoselski's fixed point theorem even holds without the assumption of X being uniformly convex. Even much more general so-called Krasnoselski-Mann iterations

$$x_{k+1} := (1 - \lambda_k)x_k + \lambda_k f(x_k)$$

are allowed, where λ_k is a sequence in $[0, 1]$ which is divergent in sum and satisfies $\limsup_{k\to\infty} \lambda_k < 1$.

In particular, it is proved in [16] that for such iterations

$$\text{(I)} \quad \lim_{k\to\infty} \|x_k - f(x_k)\| = 0,$$

where X is an arbitrary normed linear space, C a bounded convex subset of X and $f : C \to C$ is nonexpansive.

This result is further generalized in [4] to the case where C no longer is required to be bounded. Then one has

$$\text{(II)} \quad \lim_{k\to\infty} \|x_k - f(x_k)\| = r_C(f),$$

where

$$r_C(f) := \inf_{x\in C} \|x - f(x)\|$$

will in general be strictly positive.

We give a complete quantitative analysis of (II) (see theorem 4.5) as an instance of our general result on the extractability of bounds from proofs using $\text{PCM}(a_k)$ for a sequence $(a_k)_{k\in\mathbb{N}}$ which is definable in the parameters of the problem. In the case at hand $(a_k)_{k\in\mathbb{N}}$ is just $(\|x_k - f(x_k)\|)_{k\in\mathbb{N}}$. We then specialize the resulting bound to the

---

[8]See also the discussion at the end of this paper.

9

case where C is bounded and derive a uniform bound for (I) which only depends on ε, an upper bound d_C for the diameter $d(C)$ of C and some quite weak information on (λ_k) (see corollary 4.6).

None of the papers [16],[8],[11],[4] contains any bounds and in fact [8] and [11] use non-trivial functional theoretic embeddings to show (ineffectively) the existence of a common number $k \in \mathbb{N}$ which satisfies $\|x_k - f(x_k)\| < \varepsilon$ uniformly for all starting points x_0 ([8])[9] and all nonexpansive functions f ([11]). This uniformity comes for free out of our proof analysis. Moreover, as already mentioned we also have a new strong uniformity concerning C as the bounds only depend on d_C and to some extent also a uniformity w.r.t. (λ_k) (corollary 4.8). All this shows that the authors of the papers listed were not aware of the uniform bounds hidden in their proofs (note that the proof in [16] essentially is contained as a special case in the proof from [4] we are analyzing, so that the logical analysis of the former is even simpler than our proof analysis for the stronger result (II)). Only in the special case of $\lambda_k = \lambda$ being constant a uniform (and in fact optimal quadratic) bound was known before (in 1996) by [1], however, with an extremely complicated proof involving computer assisted parts.[10] This clearly indicates the usefulness of analysing noneffective proofs logically even if one is not particularly interested in the numerical details of the bounds themselves (or the bounds obtained happen to be too bad to be useful in practice). In many cases such explicit bounds immediately show the independence of the quantity in question from certain input data.[11]

3   Effective uniform bounds on the Krasnoselski iteration in uniformly convex spaces

Definition 3.1 *Let $(X, \|\cdot\|)$ be a normed linear space and $S \subseteq X$ be a subset of X. A function $f : S \to S$ is called nonexpansive if*

$$(*) \ \forall x, y \in S(\|f(x) - f(y)\| \leq \|x - y\|).$$

---

[9]This paper only considers the special case where $\lambda_k := \lambda$ is constant.

[10]In this paper, again the noneffectivity of all the proofs mentioned above is stressed.

[11]Another example for this: the explicit uniform constants of strong unicity for Chebycheff approximation which we extracted in [21],[22] by analysing classical uniqueness proofs for the best Chebycheff approximation (known already since about 1905-1917) immediately implied the existence of a common constant of unicity for compact sets K of functions $f \in C[a,b]$, if $\inf_{f \in K} dist(f, H) > 0$ (H a Haar space), a fact that was proved in approximation theory only in 1976 without providing any bounds (see [15]).

Definition 3.2 ([6]) *A normed linear space $(X, \|\cdot\|)$ is called uniformly convex if*

$$\forall \varepsilon > 0 \exists \delta > 0 \forall x, y \in X(\|x\|, \|y\| \leq 1 \wedge \|x - y\| \geq \varepsilon \to \|\frac{1}{2}(x + y)\| \leq 1 - \delta).$$

A function $\eta : (0, 2] \to (0, 1]$ providing such a $\delta := \eta(\varepsilon) > 0$ for given $\varepsilon > 0$ is called a modulus of uniform convexity.

The following fundamental existence theorem for fixed points of nonexpansive mappings and uniformly convex Banach spaces was proved independently by Browder, Göhde and Kirk (note that no compactness assumption is made in this result):

Theorem 3.3 ([5],[13],[17]) *Let $(X, \|\cdot\|)$ be a uniformly convex Banach space, $C \subseteq X$ a non-empty convex closed and bounded subset of X and $f : C \to C$ a nonexpansive mapping. Then f has a fixed point.*[12]

Another fundamental theorem in the fixed point theory for nonexpansive mappings is the following result due to Krasnoselski, which shows that (under an additional compactness condition, which by the Schauder fixed point theorem guarantees the existence of a fixed point) a fixed point of f can be approximated by a special iteration sequence:

Theorem 3.4 (Krasnoselski [30]) *Let K be a non-empty convex closed and bounded set in a uniformly convex Banach space $(X, \|\cdot\|)$ and f a nonexpansive mapping of K into a compact subset of K. Then for every $x_0 \in K$, the sequence*

$$x_{k+1} := \frac{x_k + f(x_k)}{2}$$

converges to a fixed point $z \in K$ of f.

Remark 3.5 *Note that the iteration $x_{k+1} := f(x_k)$ from the Banach fixed point theorem in general fails to converge in the setting of theorem 3.4: Take $X := \mathbb{R}$ (with the absolute value as norm), $K := [0, 1]$ and $f(x) := 1 - x$. X is uniformly convex, K is compact and convex, and $f : K \to K$ is nonexpansive, but the sequence defined by $x_0 := 0$, $x_{k+1} := f(x_k)$ alternates between 0 and 1.*

---

[12]For a nice counterexample showing that the assumption of X being uniformly convex is necessary, see [7](p.37).

One can show that there cannot be an effective procedure to compute a rate of convergence of the iteration in the Krasnoselski fixed point theorem uniformly in f and the starting point $x \in K$ of the iteration (see [29]). This already holds for the special case of $X := \mathbb{R}$ and $K := [0, 1]$ and the fixed starting point $x_0 := 0$ as there exists no computable function F from the set of all nonexpansive functions $f : [0, 1] \to [0, 1]$ into $[0, 1]$ which computes uniformly in f a fixed point of f (this is closely related to the fact that such a function F cannot be continuous with respect to the maximum norm $\|f\|_\infty$). Logically, this ineffectivity in Krasnoselski's theorem corresponds to the fact the statement that $(x_k)_{k \in \mathbb{N}}$ converges is Π^0_3.

On the other hand if we consider the weaker question of how far we have to go in the iteration to obtain an ε-fixed point, then we notice that the logical form of the statement

$$(*) \ \forall k \in \mathbb{N} \exists n \in \mathbb{N}(\|x_n - f(x_n)\| < \frac{1}{k+1})$$

is Π^0_2 (assuming that real numbers are represented as Cauchy sequences with fixed rate of convergence so that $<_{\mathbb{R}} \in \Sigma^0_1$) and hence we can find a witness n by unbounded search (effectively in $k, f, \|\cdot\|$ and the starting point of the iteration). In the following we extract a bound (and hence in view of lemma 3.8 below a realization) for n from the standard proof of theorem 3.4 (and hence of its corollary $(*)$) as it is given in [3].

Definition 3.6 *Let $(X, \|\cdot\|)$ be a normed linear space, S a subset of X, $f : S \to S$ and $\varepsilon > 0$. A point $x \in S$ is called ε-fixed point of f if $\|x - f(x)\| \le \varepsilon$.*

Lemma 3.7 *Let $(X, \|\cdot\|)$ be a normed linear space, $\emptyset \ne C \subseteq X$ convex with bounded diameter $d(C) < \infty$ and $f : C \to C$ nonexpansive. Then f has ε-fixed points in C for every $\varepsilon > 0$.*

Proof: To reduce the situation to the Banach fixed point theorem we use the following well-known construction (see e.g. [4] but also [13]): $f_t(x) := (1 - t)f(x) + tc$ for some $c \in C$ and $t \in (0, 1]$. $f_t : C \to C$ is a contraction and therefore Banach's fixed point theorem applies. Note furthermore that the completeness assumption in Banach's theorem is needed only to guarantee the existence of a limit of the Cauchy sequence $(f^n_t(c))_{n \in \mathbb{N}}$, where f^n_t denotes the n-times iteration of f_t, which is not necessary to ensure that $f^n_t(c)$ is an ε-fixed point of f_t for sufficiently large n and hence (for $t := \varepsilon/d(C)$) a 2ε-fixed point of f. That is why we don't have to assume that X is complete or that C is closed. $\square$

The following lemma belongs to the 'folklore' of the subject. We include its simple proof for the sake of completeness.

Lemma 3.8 *Let $(X, \|\cdot\|)$ be a normed linear space, $C \subseteq X$ be a convex subset of X and $f : C \to C$ a nonexpansive function. Let $x_0 \in C$ be arbitrary and define $x_{k+1} := \frac{x_k + f(x_k)}{2}$. Then*

$$\forall k(\|x_{k+1} - f(x_{k+1})\| \leq \|x_k - f(x_k)\|).$$

Proof:

$$\|x_{k+1} - f(x_{k+1})\| = \|\tfrac{1}{2}x_k + \tfrac{1}{2}f(x_k) - f(\tfrac{1}{2}x_k + \tfrac{1}{2}f(x_k))\| =$$

$$\|(\tfrac{1}{2}x_k - \tfrac{1}{2}f(x_k)) + (f(x_k) - f(\tfrac{1}{2}x_k + \tfrac{1}{2}f(x_k)))\| \leq$$

$$\|\tfrac{1}{2}x_k - \tfrac{1}{2}f(x_k)\| + \|f(x_k) - f(\tfrac{1}{2}x_k + \tfrac{1}{2}f(x_k))\| \leq$$

$$\|\tfrac{1}{2}x_k - \tfrac{1}{2}f(x_k)\| + \|x_k - (\tfrac{1}{2}x_k + \tfrac{1}{2}f(x_k))\| =$$

$$\tfrac{1}{2}\|x_k - f(x_k)\| + \tfrac{1}{2}\|x_k - f(x_k)\| = \|x_k - f(x_k)\|. \quad \square$$

Quantitative analysis of the proof of theorem 3.4 in [3]:

We now give two quantitative versions of the consequence $(*)$ of theorem 3.4. The first one follows directly the proof of the theorem as given in [3]. The second one uses a logical modification of that proof which is motivated by our general elimination procedure for PCM_{ar}. This second analysis allows to take into account in a very easy way a property which is satisfied by many moduli of uniform convexity, e.g. for all spaces L_p with $p \geq 2$, which makes it possible to improve the results obtained from the first, direct analysis for such spaces.

General logical preliminaries:

Let us for the moment assume that K itself is compact. In Bonsall's [3] proof of theorem 3.4 the following is established (where $x_0 := x$, $x_{k+1} := (x_k + f(x_k))/2$ is the Krasnoselski iteration starting from x):

$$\forall x \in K \forall \varepsilon > 0 (\exists y \in K(f(y) = y) \wedge \forall k(\|f(x_k) - x_k\| \geq \varepsilon) \to \lim_{n \to \infty} \|x_n - y\| = 0)$$

and hence

$$\forall x \in K \forall \varepsilon > 0 (\exists y \in K(f(y) = y) \wedge \forall k(\|f(x_k) - x_k\| \geq \varepsilon) \to \exists n(\|x_n - y\| < \varepsilon)),$$

where the existence of a fixed point $y \in K$ is derived from the Schauder fixed point theorem. This can be rephrased in the following form

$$\forall x, y \in K \forall \varepsilon > 0 \exists k, n, l \in \mathbb{N}$$
$$\underbrace{\left(\|f(y) - y\| \leq \frac{1}{l+1} \wedge \|f(x_k) - x_k\| \geq \varepsilon \to \exists \tilde{n} \leq n(\|x_{\tilde{n}} - y\| < \varepsilon) \right)}_{\in \Sigma_1^0}.$$

By our general results on the extractability of uniform bounds we know a priori (using the compactness of K as well as of the space of all nonexpansive mappings $f : K \to K$) that we can extract bounds $K(\varepsilon), N(\varepsilon), L(\varepsilon)$ (and hence because of the monotonicity in k, n, l of the formula above, which follows from lemma 3.8, also realizations) for k, n, l which are independent of $x, y \in K$ and f and only depend on $\varepsilon > 0$ (and a modulus of uniform convexity η of X). Since we may assume that $L(\varepsilon) > \frac{1}{\varepsilon}$ and since by the nonexpansivity of f

$$\|f(y) - y\| \leq \varepsilon \wedge \|x_{\tilde{n}} - y\| \leq \varepsilon \to \|f(x_{\tilde{n}}) - x_{\tilde{n}}\| \leq 3\varepsilon,$$

this yields

$$\exists n \leq \max\left(K(\varepsilon), N(\varepsilon)\right)(\|f(x_n) - x_n\| \leq 3\varepsilon)$$

and so again by lemma 3.8

$$\forall n \geq \max\left(K(\varepsilon), N(\varepsilon)\right)(\|f(x_n) - x_n\| \leq 3\varepsilon).$$

Thus we have obtained a uniform bound and at the same time reduced the assumption '$\exists y \in K(f(y) = y)$' to '$\forall \varepsilon > 0 \exists y \in K(\|f(y) - y\| < \varepsilon)$'. In particular, as the bound does not depend on y, the computation of such an approximate fixed point and hence an analysis of the proof of its existence is not needed.

The actual extraction of the bound carried out below reveals that such uniform bounds K, N, L even exist when the compactness assumption on K is replaced by the boundedness of K. Since by lemma 3.7 the existence of approximate fixed points (but not of fixed points) in this much more general setting is even guaranteed for spaces X which are not complete, we can remove this assumption as well and the result is proved without appeal to any fixed point theorem other than Banach's (actually only its ε-version):

Theorem 3.9 (Direct analysis of Bonsall's [3] proof of theorem 3.4)
Let $(X, \|\cdot\|)$ be a uniformly convex normed space with modulus of convexity $\eta : (0,2] \to (0,1]$ and $C \subseteq X$ be a non-empty convex set with

$$d(C) := \sup_{x_1, x_2 \in C} \|x_1 - x_2\| \leq d_C \in \mathbb{Q}_+^*.$$

14

Let $f : C \to C$ be a nonexpansive function.
Define for arbitrary $x \in C$

$$x_0 := x, \quad x_{k+1} := \frac{x_k + f(x_k)}{2}.$$

Then

$$\forall x \in C \forall \varepsilon > 0 \forall k \geq h(\varepsilon, d_C)(\|x_k - f(x_k)\| \leq \varepsilon),$$

where $h(\varepsilon, d_C) := \left\lceil \frac{\ln(4d_C) - \ln(\varepsilon)}{\eta(\varepsilon/(d_C + 1))} \right\rceil$ for $\varepsilon < d_C$ and $h(\varepsilon, d_C) := 0$ otherwise.

Proof: The theorem is trivial for $\varepsilon \geq d_C$. So we can assume that $\varepsilon < d_C$. By lemma 3.7, f has ε-fixed points $x_\varepsilon \in C$, $\|f(x_\varepsilon) - x_\varepsilon\| < \varepsilon$ for every $\varepsilon > 0$. Let $\delta > 0$ be such that $\delta < \min(1, \frac{\varepsilon}{12h(\varepsilon, d_C)})$ and let $y \in C$ be a δ-fixed point of f, i.e.

$$(1) \ \|y - f(y)\| < \delta.$$

Assume that

$$(2) \ \|x_k - f(x_k)\| = \|(x_k - y) - (f(x_k) - y)\| > \varepsilon.$$

Then

$$(3) \ \left\| \frac{x_k - y}{\|x_k - y\| + \delta} - \frac{f(x_k) - y}{\|x_k - y\| + \delta} \right\| > \frac{\varepsilon}{\|x_k - y\| + \delta} \geq \frac{\varepsilon}{d_C + 1}.$$

Because of

$$(4) \ \|f(x_k) - y\| \overset{(1)}{\leq} \|f(x_k) - f(y)\| + \delta \leq \|x_k - y\| + \delta,$$

we have

$$(5) \ \left\| \frac{x_k - y}{\|x_k - y\| + \delta} \right\|, \left\| \frac{f(x_k) - y}{\|x_k - y\| + \delta} \right\| \leq 1$$

and therefore

$$(6) \ \left\| \frac{1}{2} \left(\frac{x_k - y}{\|x_k - y\| + \delta} + \frac{f(x_k) - y}{\|x_k - y\| + \delta} \right) \right\| \leq 1 - \eta(\varepsilon/(d_C + 1)).$$

Hence

$$(7) \ \begin{cases} \|x_{k+1} - y\| = \|\frac{1}{2}(x_k + f(x_k)) - y\| = \|\frac{1}{2}(x_k - y + f(x_k) - y)\| \leq \\ (1 - \eta(\varepsilon/(d_C + 1)))(\|x_k - y\| + \delta). \end{cases}$$

15

Therefore, if (2) holds for all $k \leq k_0 := h(\varepsilon, d_C) - 1$ then

$$(8) \begin{cases} \|x_{k_0+1} - y\| \leq (1 - \eta(\varepsilon/(d_C + 1)))^{k_0+1}\|x_0 - y\| + \sum_{i=1}^{k_0+1}(1 - \eta(\varepsilon/(d_C + 1)))^i \cdot \delta \\ \leq (1 - \eta(\varepsilon/(d_C + 1)))^{k_0+1} \cdot d_M + (k_0 + 1)\delta \leq (1 - \eta(\varepsilon/(d_C + 1)))^{k_0+1} \cdot d_C + \frac{\varepsilon}{12}. \end{cases}$$

We now show that

$$(9)\ (1 - \eta(\varepsilon/(d_C + 1)))^{k_0+1} \cdot d_C \leq \frac{\varepsilon}{4}.$$

Proof of (9): If $\eta(\varepsilon/(d_C + 1)) = 1$, then the claim holds trivially. Otherwise, (9) is equivalent to

$$k_0 + 1 \geq \frac{\ln(\varepsilon/4d_C)}{\ln(1 - \eta(\varepsilon/(d_C + 1)))}.$$

Since $\ln(1) = 0$ and $\frac{d}{dx}\ln(x) = \frac{1}{x} \geq 1$ for all $x \in (0, 1]$, we get

$$-\ln(1 - \eta(\varepsilon/(d_C + 1))) \geq \eta(\varepsilon/(d_C + 1)).$$

Together with $-\ln(\varepsilon/4d_C) = \log(4d_C) - \ln(\varepsilon)$ this yields (9).

(8) and (9) together imply

$$(10)\ \forall k \leq h(\varepsilon, d_C) - 1(\|x_k - f(x_k)\| > \varepsilon) \to \|x_{h(\varepsilon,d_C)} - y\| \leq \frac{\varepsilon}{3}.$$

Since f is nonexpansive and y is an $\frac{\varepsilon}{3}$-fixed point of f the right-hand side of the implication yields $\|x_{h(\varepsilon,d_C)} - f(x_{h(\varepsilon,d_C)})\| \leq \varepsilon$. So

$$(11)\ \exists k \leq h(\varepsilon, d_C)(\|x_k - f(x_k)\| \leq \varepsilon)$$

and hence by lemma 3.8 above

$$(12)\ \forall k \geq h(\varepsilon, d_C)(\|x_k - f(x_k)\| \leq \varepsilon),$$

which concludes the proof of the theorem. $\square$

Theorem 3.10 (Analysis of a modification of Bonsall's [3] proof of thm.3.4)

Under the same hypotheses as in theorem 3.9 we obtain

$$\forall x \in C \forall \varepsilon > 0 \forall k \geq h(\varepsilon, d_C)(\|x_k - f(x_k)\| \leq \varepsilon),$$

16

where $h(\varepsilon, d_C) := \left\lceil \frac{4 \cdot d_C}{\varepsilon \cdot \eta(\frac{\varepsilon}{d_C+1})} \right\rceil$ for $\varepsilon < d_C$ and $h(\varepsilon, d_C) := 0$ otherwise.

Moreover, if $\eta(\varepsilon)$ can be written as $\eta(\varepsilon) = \varepsilon \cdot \tilde{\eta}(\varepsilon)$ with

$$(*) \quad \forall \varepsilon_1, \varepsilon_2 > 0 (\varepsilon_1 \geq \varepsilon_2 \to \tilde{\eta}(\varepsilon_1) \geq \tilde{\eta}(\varepsilon_2)),$$

then the bound $h(\varepsilon, d_C)$ can be replaced (for $\varepsilon < d_C$) by

$$\tilde{h}(\varepsilon, d_C) := \left\lceil \frac{2 \cdot d_C}{\varepsilon \cdot \tilde{\eta}(\frac{\varepsilon}{d_C+1})} \right\rceil.$$

Proof: By lemma 3.7, f has ε-fixed points $x_\varepsilon \in C$, $\|f(x_\varepsilon) - x_\varepsilon\| < \varepsilon$ for every $\varepsilon > 0$. Let $\delta > 0$ be such that $\delta < \min(1, \frac{\varepsilon}{3}, \frac{\varepsilon}{12} \cdot \eta(\varepsilon/(d_C + 1)))$ and let $y \in C$ be a δ-fixed point of f, i.e.

$$(1) \quad \|y - f(y)\| < \delta.$$

Assume that

$$(2) \quad \|x_k - y\| \geq \frac{\varepsilon}{3} \text{ and}$$

$$(3) \quad \|x_k - f(x_k)\| = \|(x_k - y) - (f(x_k) - y)\| > \varepsilon.$$

As in the proof of theorem 3.9 one shows that

$$(4) \quad \left\| \frac{1}{2} \left(\frac{x_k - y}{\|x_k - y\| + \delta} + \frac{f(x_k) - y}{\|x_k - y\| + \delta} \right) \right\| \leq 1 - \eta(\varepsilon/(d_C + 1)).$$

Hence

$$(5) \quad \begin{cases} \|x_{k+1} - y\| = \|\frac{1}{2}(x_k + f(x_k)) - y\| = \|\frac{1}{2}(x_k - y + f(x_k) - y)\| \leq \\ \|x_k - y\| + \delta - (\|x_k - y\| + \delta) \cdot \eta(\varepsilon/(d_C + 1)) \overset{(2)}{\leq} \\ \|x_k - y\| + \delta - \frac{\varepsilon}{3} \cdot \eta(\varepsilon/(d_C + 1)) \leq \|x_k - y\| - \frac{\varepsilon}{4} \cdot \eta(\varepsilon/(d_C + 1)). \end{cases}$$

Define

$$n_\varepsilon := \left\lceil \frac{d_C}{\frac{\varepsilon}{4} \cdot \eta(\varepsilon/(d_C + 1))} \right\rceil = \left\lceil \frac{4 \cdot d_C}{\varepsilon \cdot \eta(\varepsilon/(d_C + 1))} \right\rceil.$$

If $(2), (3)$ both hold for all $k \leq n_\varepsilon$, then (5) yields

$$(6) \quad \|x_{n_\varepsilon+1} - y\| < \|x_0 - y\| - d_C,$$

17

which contradicts the choice of d_C by which $\|x_k - y\| \in [0, d_C]$ for all $k \in \mathbb{N}$. Hence

$$(7) \quad \exists k \leq n_\varepsilon(\|x_k - y\| \leq \frac{\varepsilon}{3} \vee \|x_k - f(x_k)\| \leq \varepsilon).$$

By the choice of δ, (1) and the nonexpansivity of f, the first disjunct also implies that $\|f(x_k) - x_k\| \leq \varepsilon$ and so by the preceding lemma

$$(8) \quad \forall k \geq n_\varepsilon(\|x_k - f(x_k)\| \leq \varepsilon).$$

The last claim in the theorem follows by choosing $y \in C$ as a δ-fixed point of f with $\delta < \min(1, \frac{\varepsilon}{3}, \frac{\varepsilon}{2} \cdot \tilde{\eta}(\varepsilon/(d_C + 1)))$ and the following modifications of $(4), (5)$ to

$$(4)^* \quad \left\| \frac{1}{2} \left(\frac{x_k - y}{\|x_k - y\| + \delta} + \frac{f(x_k) - y}{\|x_k - y\| + \delta} \right) \right\| \leq 1 - \eta(\varepsilon/(\|x_k - y\| + \delta)).$$

$$(5)^* \quad \begin{cases} \|x_{k+1} - y\| = \|\frac{1}{2}(x_k + f(x_k)) - y\| = \|\frac{1}{2}(x_k - y + f(x_k) - y)\| \leq \\[4pt] \|x_k - y\| + \delta - (\|x_k - y\| + \delta) \cdot \eta(\varepsilon/(\|x_k - y\| + \delta)) = \\[4pt] \|x_k - y\| + \delta - \varepsilon \cdot \tilde{\eta}(\varepsilon/(\|x_k - y\| + \delta)) \overset{(*)}{\leq} \|x_k - y\| + \delta - \varepsilon \cdot \tilde{\eta}(\varepsilon/(d_C + 1)) \\[4pt] \leq \|x_k - y\| - \frac{\varepsilon}{2} \cdot \tilde{\eta}(\varepsilon/(d_C + 1)) \end{cases}$$

(note that we can apply η to $\varepsilon/(\|x_k - y\| + \delta)$ since (3) and

$$\|f(x_k) - y\| \overset{(1)}{\leq} \|f(x_k) - f(y)\| + \delta \leq \|x_k - y\| + \delta$$

imply

$$\varepsilon \leq \|x_k - y\| + \|f(x_k) - y\| \leq 2(\|x_k - y\| + \delta)$$

and therefore

$$\varepsilon/(\|x_k - y\| + \delta) \in (0, 2]).$$

$\square$

If we disregard for a moment the diameter estimate d_C in the bounds in theorems 3.9 and 3.10 and put $\varepsilon := 2^{-n}$, then we see that the bound from theorem 3.9 essentially is $n/\eta(2^{-n})$, whereas the first bound in theorem 3.10 is only about $2^n/\eta(2^{-n})$. If, however, $\eta(\varepsilon)$ can be written as $\varepsilon \cdot \tilde{\eta}(\varepsilon)$ with $\tilde{\eta}$ satisfying $(*)$, then theorem 3.10 roughly gives $1/\eta(2^{-n})$ which is better than the bound from theorem 3.9. It is this fact that we will use in the example below to obtain a polynomial bound for L_p

18

$(p \geq 2)$ which is of degree p.

Examples: It is well-known that the Banach spaces L_p with $1 < p < \infty$ are uniformly convex (this was first proved in [6], see also [20]). For $p \geq 2$, the following explicit modulus η_p of uniform convexity was obtained in [14]

$$\eta_p(\varepsilon) := 1 - (1 - (\varepsilon/2)^p)^{1/p}.$$

One easily shows (using the derivative of $x^{1/p}$) that (for $(0, 2]$)

$$\eta_p(\varepsilon) \geq \frac{\varepsilon^p}{p2^p}.$$

Hence $\frac{\varepsilon^p}{p2^p}$ is a modulus of convexity as well. Since

$$\frac{\varepsilon^p}{p2^p} = \varepsilon \cdot \tilde{\eta}_p(\varepsilon)$$

with

$$\tilde{\eta}_p(\varepsilon) = \frac{\varepsilon^{p-1}}{p2^p}$$

satisfying $(*)$ in the theorem above, we obtain the following

Corollary 3.11 *Let $p \geq 2$, $C \subseteq L_p$ a non-empty convex subset with $d(C) \leq d_C \in Q_+^*$, $f : C \to C$ nonexpansive and $(x_k)_{k \in \mathbb{N}}$ defined as in the theorem. Then*

$$\forall x \in C \forall \varepsilon > 0 \forall k \geq \left\lceil \frac{d_C p (d_C + 1)^{p-1} 2^{p+1}}{\varepsilon^p} \right\rceil (\|x_k - f(x_k)\| \leq \varepsilon).$$

Note the bound in corollary 3.11 only depends on p, ε and an upper bound d_C of $d(C)$ but not on $x \in C$ or f.

For the case $X := \mathbb{R}, C := [0, 1]$, theorem 3.10 even gives a linear bound, since $\varepsilon/2$ is a modulus of uniform convexity in this case and $\tilde{\eta}(\varepsilon) := \frac{1}{2}$ satisfies $(*)$.

Remark 3.12 Our result in corollary 3.11 can easily be improved by replacing $(d_C + 1)$ by $(d_C + \delta)$ for any $\delta > 0$ and so in the limit by d_C. In [18], using a direct calculation based on the modulus of uniform convexity for L_p, essentially the same result is obtained (only with a better constant as the factor '$p2^{p+1}$' is missing). For a linear bound in the case $[0, 1]$, [18] refer to an unpublished result of J. Alexander. Note, however, that our bounds in these examples, where derived just as a special case from the general bound in theorem 3.10.

4 Effective uniform bounds on the Krasnoselski-Mann iteration in arbitrary normed spaces

Throughout this section, $(X, \|\cdot\|)$ will be an arbitrary normed linear space, $C \subseteq X$ a non-empty convex subset of X and $f : C \to C$ a nonexpansive mapping.

We consider the so-called Krasnoselski-Mann iteration (which is more general than the Krasnoselski iteration and due to Mann [33]) generated starting from an arbitrary $x \in C$ by

$$x_0 := x, \quad x_{k+1} := (1 - \lambda_k)x_k + \lambda_k f(x_k),$$

where $(\lambda_k)_{k \in \mathbb{N}}$ is a sequence of real numbers in $[0, 1]$. For background information on this iteration and plenty of references see [4].

Lemma 4.1 ([4]) *For all $k \in \mathbb{N}$ and $x, x^* \in C$:*

1) $\|x_{k+1} - f(x_{k+1})\| \le \|x_k - f(x_k)\|$,

2) $\|x_{k+1} - x_{k+1}^*\| \le \|x_k - x_k^*\|$.

Proof: 1) Similarly to lemma 3.8 above.

2) $\|x_{k+1} - x_{k+1}^*\| = \|(1 - \lambda_k)(x_k - x_k^*) + \lambda_k(f(x_k) - f(x_k^*))\| \le$
$(1 - \lambda_k)\|x_k - x_k^*\| + \lambda_k\|f(x_k) - f(x_k^*)\| \le \|x - x^*\|$, because of the non-expansivity of f. $\square$

For the results in this section we assume (following [4]) that $(\lambda_k)_{k \in \mathbb{N}}$ is divergent in sum, which can be expressed (since $\lambda_k \ge 0$) as

$$(A) \ \forall n, i \in \mathbb{N} \exists k \in \mathbb{N} \left(\sum_{j=i}^{i+k} \lambda_j \ge n \right).$$

We also assume (again as in [4]) that

$$(B) \ \limsup_{k \to \infty} \lambda_k < 1.$$

Define

$$r_C(f) := \inf_{x \in C} \|x - f(x)\|.$$

Theorem 4.2 ([4]) [13] *Suppose that $(\lambda_k)_{k\in\mathbb{N}}$ satisfies the conditions (A) and (B). Then for any starting point $x \in C$ and the Krasnoselski-Mann iteration (x_n) starting from x we have*

$$\|x_n - f(x_n)\| \stackrel{n\to\infty}{\to} r_C(f).$$

Corollary 4.3 ([16],[11],[4]) *Under the assumptions of theorem 4.2 plus the additional assumption that C has bounded diameter $d(C) < \infty$ the following holds:*

$$\forall x \in C \forall \varepsilon > 0 \exists n \mathbb{N} \forall m \geq n (\|x_m - f(x_m)\| \leq \varepsilon).$$

Proof: Follows from theorem 4.2 and lemma 3.7. □

Remark 4.4 In [11] it is actually shown that one can choose n in the corollary independently of $x \in C$ and f. Whereas in [11] a complicated functional theoretic embedding into the space of all nonexpansive mappings is used to derive this uniformity statement, it trivially follows from our quantitative analysis in corollary 4.6 below which even provides an explicit effective description of such a uniform n. For a more restricted iteration the existence of a bound n independent of x was also obtained by [8] using, however, also a universal embedding theorem (due to Banach and Mazur). The use of non-trivial functional theoretic arguments in [11] and [8] to obtain the (ineffective) existence of a uniform n clearly indicates that the authors were not aware of explicit effective uniform bounds hidden in the proof of $\lim_{k\to\infty}\|f(x_k) - x_k\| = 0$ as given e.g. in [11] and its generalization in [4] which we will analyze now.[14]

Quantitative analysis of the proof of theorem 4.2 in [4]:

General logical preliminaries:

As we have discussed above, we only can expect to be able to extract a bound $\forall x \exists y \leq \Phi(x) A(x,y)$ from a non-constructive proof if A is a purely existential formula. Since the statement in theorem 4.2 involves two implicative assumptions on $(\lambda_k)_{k\in\mathbb{N}}$ as well as the existence of $r_C(f)$, it prima facie does not have the required form. However, it can be reformulated such as to have the right logical form by enriching the input $(\lambda_k)_{k\in\mathbb{N}}, f, x, \varepsilon$ by additional data $K \in \mathbb{N}, \alpha : \mathbb{N} \times \mathbb{N} \to \mathbb{N}$ and $x^* \in C$. Let us first examine conditions (A) and (B) on $(\lambda_k)_{k\in\mathbb{N}}$:

---

[13]With the additional assumption that λ_k is bounded away from zero, this result is also proved in [34].

[14]For a more detailed discussion, see the final section of this paper.

An explicit version of (A) asks for a function $\alpha : \mathbb{N} \times \mathbb{N} \to \mathbb{N}$ realizing the existential quantifier, i.e.

$$(A_\alpha) \ \forall n, i \in \mathbb{N} \left(\sum_{j=i}^{i+\alpha(i,n)} \lambda_j \geq n \right).$$

(B) states the existence of a $K \in \mathbb{N}$ such that

$$\lambda_k \leq 1 - \frac{1}{K}$$

from some index k_0 on. Since k_0 only contributes an additive constant to our bound we may assume for simplicity that $k_0 = 0$. So let

$$(B_K) \ \forall k \in \mathbb{N}(\lambda_k \leq 1 - \frac{1}{K}).$$

We now formulate the theorem more explicitly as follows:

$$(*) \begin{cases} \forall (\lambda_k) \in [0,1]^{\mathbb{N}} \forall f : C \to C \forall x, x^* \in C \forall K, \alpha \forall \varepsilon > 0 \exists n \in \mathbb{N} \\ (f \text{ nonexpans.} \wedge (A_\alpha) \wedge (B_K) \to \|x_n - f(x_n)\| < \|x^* - f(x^*)\| + \varepsilon). \end{cases}$$

Note that by lemma 4.1.1), $(*)$ immediately implies theorem 4.2.
By our representation of real numbers by which $\leq_{\mathbb{R}} \in \Pi_1^0$ and $<_{\mathbb{R}} \in \Sigma_1^0$, the implication

$$(f \text{ nonexpansive} \wedge (A_\alpha) \wedge (B_K) \to \|x_n - f(x_n)\| < \|x^* - f(x^*)\| + \varepsilon)$$

is equivalent to a purely existential formula. The proof of $(*)$ only uses tools formalizable in **EBA** plus the principle $\text{PCM}(\|x_k - f(x_k)\|)$ (discussed in the introduction) applied to $(\|x_k - f(x_k)\|)_{k \in \mathbb{N}}$ and a complicated inequality due to [11]. This inequality can be treated just as another purely universal implicative premise and does therefore not increase the logical complexity of the theorem (nor is its proof needed to be analysed). Since, furthermore, the Hilbert cube $[0,1]^{\mathbb{N}}$ is a compact space, our general results discussed discussed in the introduction guarantee (at least for complete separable X and definable C)[15] the existence of an effective bound for n which does not depend on (λ_k) directly but which may possibly depend on $K, \alpha, x, x^*, f, \varepsilon$

---

[15] The actually extracted bound will in fact turn out to be valid for arbitrary normed linear spaces X and convex subsets $C \subset X$. Note that the convexity assumption on C is purely universal.

and γ. This information on what type of result we should look for is a significant application of our logical approach to the specific proof of theorem 4.2 which would not have been visible without the reformulation of the theorem focusing on its logical form.

We also know a-priori from our general logical meta-theorem, that a uniform bound on n which does not depend on $x, x^* \in C, \gamma > 0$ and f is extractable **if** C is compact (and hence has bounded diameter). For the bound we actually extract, the dependence on x, x^*, f, γ can already be eliminated as soon as we have an upper bound on the diameter $d(C)$ of C. This stronger uniformity result is an a-postiori information we get for free just by examining the extracted bound (compare this with remark 4.4 and the discussion in the final section of this paper).

Extraction of the bound:

We now proceed to the actual extraction of the bound from the proof of theorem 4.2 which we present here in a usual mathematical style without following step by step a fixed proof theoretic procedure.

Let $x^* \in C$ and define

$$(1) \ \gamma := \|x^* - f(x^*)\|.$$

Let furthermore $\varepsilon > 0$ and $x \in C$ be arbitrary and let $M \in \mathbb{N}$ be such that

$$(2) \ M \geq \frac{1 + 2\|x - x^*\|}{\varepsilon}.$$

Let $\delta > 0$ be so small that

$$(3) \ \delta \exp(K(M + 1)) < 1,$$

where $K \in \mathbb{N}$ satisfies

$$(4) \ \forall k \in \mathbb{N}(\lambda_k \leq 1 - \frac{1}{K}).$$

Let $\alpha : \mathbb{N} \times \mathbb{N} \to \mathbb{N}$ be such that[16]

$$(5) \ \forall i, n \in \mathbb{N}(n \leq S_{i,\alpha(i,n)} \leq n + 1),$$

where

$$(6) \ S_{i,n} := \sum_{s=i}^{i+n-1} \lambda_s.$$

---

[16]Since $\lambda_k \in [0, 1)$ this can always be achieved.

Consider the Krasnoselski-Mann iteration $(x_n)_{n\in\mathbb{N}}$ starting from x. By lemma 4.1.1), the sequence $(\|x_n - f(x_n)\|)_{n\in\mathbb{N}} \subset [0, \|x - f(x)\|]$ is monotone decreasing and hence convergent. Thus there exists an i such that

$$(7)\ \|x_i - f(x_i)\| - \|x_{i+\alpha(i,M)} - f(x_{i+\alpha(i,M)})\| \leq \delta.$$

Suppose that

$$(8)\ \|x_i - f(x_i)\| \geq \gamma + \varepsilon.$$

The proof in [4] uses the following inequality which is derived from a fundamental inequality due to [11] and which holds for all $i, n \in \mathbb{N}$

$$(9)\ S_{i,n} \cdot \|x_i - f(x_i)\| \leq \|x_i - x_{i+n}\| + P_{i,n} \cdot (\|x_i - f(x_i)\| - \|x_{i+n} - f(x_{i+n})\|),$$

where

$$(10)\ P_{i,n} := \prod_{s=i}^{i+n-1} \frac{1}{1 - \lambda_s}.$$

As in [16] one shows that

$$(11)\ \forall i, n \in \mathbb{N}(P_{i,n} \leq \exp(K \cdot S_{i,n})).$$

In [4](p.23), the following inequality is established $((x_k^*)$ is the Krasnoselski-Mann iteration starting from x^*)

$$(12)\ \|x_i^* - x_{i+n}^*\| \leq S_{i,n} \cdot \|x_i^* - f(x_i^*)\| \overset{l.4.1.1)}{\leq} S_{i,n} \cdot \|x^* - f(x^*)\|.$$

Together with lemma 4.1.2) we obtain

$$(13)\ \begin{cases} S_{i,\alpha(i,M)} \cdot (\gamma + \varepsilon) \overset{(8)}{\leq} S_{i,\alpha(i,M)} \cdot \|x_i - f(x_i)\| \overset{(9,7)}{\leq} \|x_i - x_{i+\alpha(i,M)}\| + \delta P_{i,\alpha(i,M)} \\ \leq \|x_i - x_i^*\| + \|x_i^* - x_{i+\alpha(i,M)}^*\| + \|x_{i+\alpha(i,M)}^* - x_{i+\alpha(i,M)}\| + \delta P_{i,\alpha(i,M)} \\ \overset{4.1.2)}{\leq} 2\|x - x^*\| + \|x_i^* - x_{i+\alpha(i,M)}^*\| + \delta P_{i,\alpha(i,M)} \\ \overset{(12)}{\leq} 2\|x - x^*\| + S_{i,\alpha(i,M)} \cdot \|x^* - f(x^*)\| + \delta P_{i,\alpha(i,M)}. \end{cases}$$

Hence

$$(14)\ \begin{cases} 1 + 2\|x - x^*\| \overset{(2)}{\leq} M \cdot \varepsilon \overset{(5)}{\leq} \varepsilon S_{i,\alpha(i,M)} \\ \overset{(1)}{\leq} S_{i,\alpha(i,M)}(\gamma + \varepsilon - \|x^* - f(x^*)\|) \overset{(13)}{\leq} 2\|x - x^*\| + \delta P_{i,\alpha(i,M)} \\ \overset{(11)}{\leq} 2\|x - x^*\| + \delta \exp(K \cdot S_{i,\alpha(i,M)}) \\ \overset{(5)}{\leq} 2\|x - x^*\| + \delta \exp(K(M+1)) \overset{(3)}{<} 2\|x - x^*\| + 1, \end{cases}$$

24

which is a contradiction. Therefore $\|x_i - f(x_i)\| < \gamma + \varepsilon$.

It remains to construct a function $h(x, f, K, \alpha, M)$ which is a bound $i \le h(x, f, K, \alpha, M)$ for i in (7):

Define

$$\tilde{\alpha}(i, M) := i + \alpha(i, M)$$

and the m-times iteration $\widehat{\alpha}$ of $\lambda i.\tilde{\alpha}(i, M)$

$$\widehat{\alpha}(0, M) := \tilde{\alpha}(0, M) \text{ and } \widehat{\alpha}(m + 1, M) := \tilde{\alpha}(\widehat{\alpha}(m, M), M).$$

It is clear that

$$(15) \ \forall i(\widehat{\alpha}(i, M) \le \widehat{\alpha}(i + 1, M)).$$

Claim:[17]

$$\exists i \le \left\lceil \frac{\|x - f(x)\|}{\delta} \right\rceil \dot{-} 1 (\|x_{\widehat{\alpha}(i,M)} - f(x_{\widehat{\alpha}(i,M)})\| - \|x_{\widehat{\alpha}(i+1,M)} - f(x_{\widehat{\alpha}(i+1,M)})\| \le \delta).$$

Proof of Claim: Let $j := \left\lceil \frac{\|x - f(x)\|}{\delta} \right\rceil \dot{-} 1$ and suppose the claim is false. Then

$$\forall i \le j(\|x_{\widehat{\alpha}(i,M)} - f(x_{\widehat{\alpha}(i,M)})\| - \|x_{\widehat{\alpha}(i+1,M)} - f(x_{\widehat{\alpha}(i+1,M)})\| > \delta).$$

Since by lemma 4.1.1) the sequence $(\|x_i - f(x_i)\|)_{i \in \mathbb{N}}$ is decreasing and – by (15) – $\lambda i.\widehat{\alpha}(i, M)$ is monotone, we obtain

$$\|x_{\widehat{\alpha}(0,M)} - f(x_{\widehat{\alpha}(0,M)})\| - \|x_{\widehat{\alpha}(j+1,M)} - f(x_{\widehat{\alpha}(j+1,M)})\|$$
$$> \delta \cdot (j + 1) \ge \|x - f(x)\|,$$

which is a contradiction to the fact that $\forall n \in \mathbb{N}(\|x_n - f(x_n)\| \in [0, \|x - f(x)\|])$ and finishes the proof of the claim.

Using that

$$(16) \ \forall i(\widehat{\alpha}(i + 1, M) = \widehat{\alpha}(i, M) + \alpha(\widehat{\alpha}(i, M), M),$$

the claim yields

$$(17) \begin{cases} \exists i \le \left\lceil \frac{\|x - f(x)\|}{\delta} \right\rceil \dot{-} 1 \\ (\|x_{\widehat{\alpha}(i,M)} - f(x_{\widehat{\alpha}(i,M)})\| - \|x_{\widehat{\alpha}(i,M)+\alpha(\widehat{\alpha}(i,M),M)} - f(x_{\widehat{\alpha}(i,M)+\alpha(\widehat{\alpha}(i,M),M)})\| \le \delta). \end{cases}$$

[17] $n \dot{-} 1 := \max(0, n - 1)$.

25

Hence – using again the monotonicity of $\lambda i.\widehat{\alpha}(i, M)$ – a bound for i in $(*)$ is given by $\widehat{\alpha}(\lceil(\|x - f(x)\|/\delta)\rceil \dotminus 1, M)$. Since we can put $\delta := \frac{1}{2\exp(K(M+1))}$ we obtain

$$h(x, f, K, \alpha, M) := \widehat{\alpha}(\lceil 2\|x - f(x)\| \exp(K(M+1))\rceil \dotminus 1, M)$$

with $M \in \mathbb{N}$ such that

$$M \geq \frac{1 + 2\|x - x^*\|}{\varepsilon}$$

as bound for an i such that

$$\|x_i - f(x_i)\| < \gamma + \varepsilon$$

and therefore (using again lemma 4.1.1)

$$\forall i \geq h(x, f, K, \alpha, M)(\|x_i - f(x_i)\| < \gamma + \varepsilon).$$

We now show that we can replace (5) by the more flexible requirement[18]

$$(5)' \ \forall i, n \in \mathbb{N}(\alpha(i, n) \leq \alpha(i + 1, n) \wedge n \leq S_{i,\alpha(i,n)}).$$

Assume that α satisfies $(5)'$. Define

$$\alpha^*(i, n) := \min m \in \mathbb{N}[n \leq \sum_{s=i}^{i+m-1} \lambda_s].$$

Then

$$\forall i, n \in \mathbb{N}(n \leq S_{i,\alpha^*(i,n)} \leq n + 1),$$

since $\lambda_s \leq 1$. Hence by the logical analysis carried out so far we obtain the bound $h(\varepsilon, x, x^*, f, K, \alpha^*)$. In this bound, α^* can be replaced by α since

$$h(\varepsilon, x, x^*, f, K, \alpha^*) \leq h(\varepsilon, x, x^*, f, K, \alpha),$$

which is a consequence of

$$\forall i, n \in \mathbb{N}(\widehat{\alpha^*}(i, n) \leq \widehat{\alpha}(i, n)),$$

which can be proved by an easy induction on i.

Put together we have established the following

---

[18]Note that the first conjunct can always be achieved without violating the second one by using $\alpha_+(i, n) := \max_{j \leq i}(\alpha(j, n))$.

Theorem 4.5 *Let $(X, \|\cdot\|)$ be a normed linear space, $C \subseteq X$ a non-empty convex subset and $f : C \to C$ a nonexpansive mapping. Let $(\lambda_k)_{k\in\mathbb{N}}$ be a sequence in $[0,1]$ which is divergent in sum and satisfies*

$$\forall k \in \mathbb{N}(\lambda_k \leq 1 - \frac{1}{K})$$

for some $K \in \mathbb{N}$.
Let $\alpha : \mathbb{N} \times \mathbb{N} \to \mathbb{N}$ be such that

$$\forall i, n \in \mathbb{N}(\alpha(i,n) \leq \alpha(i+1,n)) \text{ and}$$

$$\forall i, n \in \mathbb{N}(n \leq \sum_{s=i}^{i+\alpha(i,n)-1} \lambda_s).$$

Let $(x_n)_{n\in\mathbb{N}}$ be the Krasnoselski-Mann iteration

$$x_{n+1} := (1 - \lambda_n)x_n + \lambda_n f(x_n), \ x_0 := x$$

starting from $x \in C$. Then the following holds

$$\forall x, x^* \in C \forall \varepsilon > 0 \forall n \geq h(\varepsilon, x, x^*, f, K, \alpha)(\|x_n - f(x_n)\| < \|x^* - f(x^*)\| + \varepsilon),$$

where

$$h(\varepsilon, x, x^*, f, K, \alpha) := \widehat{\alpha}(\lceil 2\|x - f(x)\| \cdot \exp(K(M+1)) \rceil \dotminus 1, M),$$
$$\text{with } M := \left\lceil \frac{1 + 2\|x - x^*\|}{\varepsilon} \right\rceil \text{ and}$$
$$\widehat{\alpha}(0, M) := \tilde{\alpha}(0, M), \ \widehat{\alpha}(m+1, M) := \tilde{\alpha}(\widehat{\alpha}(m, M), M) \text{ with}$$
$$\tilde{\alpha}(m, M) := m + \alpha(m, M) \ (m \in \mathbb{N})$$

(Instead of M we may use any upper bound $\mathbb{N} \ni \tilde{M} \geq \frac{1 + 2\|x - x^*\|}{\varepsilon}$). Likewise, we may resplace $\|x - f(x)\|$ by any upper bound).

Corollary 4.6
Let $(X, \|\cdot\|)$ be a normed linear space, $C \subseteq X$ a non-empty convex subset with bounded diameter $d(C) < \infty$ and $f : C \to C$ a nonexpansive mapping. Let $(\lambda_k)_{k\in\mathbb{N}}$ be a sequence in $[0,1]$ which is divergent in sum and satisfies

$$\forall k \in \mathbb{N}(\lambda_k \leq 1 - \frac{1}{K})$$

for some $K \in \mathbb{N}$.

Let $\alpha : \mathbb{N} \times \mathbb{N} \to \mathbb{N}$ be such that

$$\forall i, n \in \mathbb{N}(\alpha(i, n) \le \alpha(i + 1, n)) \ and$$

$$\forall i, n \in \mathbb{N}(n \le \sum_{s=i}^{i+\alpha(i,n)-1} \lambda_s).$$

Let $(x_n)_{n \in \mathbb{N}}$ be the Krasnoselski-Mann iteration

$$x_{n+1} := (1 - \lambda_n)x_n + \lambda_n f(x_n), \ x_0 := x$$

starting from $x \in C$. Then the following holds

$$\forall x \in C \forall \varepsilon > 0 \forall n \ge h(\varepsilon, d(C), K, \alpha)(\|x_n - f(x_n)\| \le \varepsilon),$$

where

$h(\varepsilon, d(C), K, \alpha) := \widehat{\alpha}(\lceil 2d(C) \cdot \exp(K(M + 1)) \rceil - 1, M), \ with \ M := \left\lceil \frac{1+2d(C)}{\varepsilon} \right\rceil \ and$

$\widehat{\alpha}(0, M) := \tilde{\alpha}(0, M), \ \widehat{\alpha}(m + 1, M) := \tilde{\alpha}(\widehat{\alpha}(m, M), M) \ with$

$\tilde{\alpha}(m, M) := m + \alpha(m, M) \ \ (m \in \mathbb{N})$

(Instead of $M, d(C)$ we may use any upper bounds $\mathbb{Q}_+^* \ni d_C \ge d(C)$ and $\mathbb{N} \ni \tilde{M} \ge \frac{1+2d_C}{\varepsilon}$).

Proof: The corollary follows from theorem 4.5 and lemma 3.7 by noticing that $\|x - f(x)\|, \|x - x^*\| \le d(C)$. $\square$

Remark 4.7 The behaviour of the bound in corollary 4.6 w.r.t. $d(C)$ can be improved as follows: if $d(C)$ is different from 1 we renorm the space by the multiplicative factor $\frac{1}{d(C)}$. Then $h(\varepsilon, 1, K, \alpha)$ gives the rate of the asymptotic regularity w.r.t. this new norm and hence $h(\frac{\varepsilon}{d(C)}, 1, K, \alpha)$ for the original norm.

This result could have been obtained also directly from the proof of theorem 4.5 above by noticing that instead of '$1 + 2\|x - x^*\|$' in (2) we could have used '$l + 2\|x - x^*\|$' for any positive l (so in particular $l := d(C)$) and then taking $\delta := \frac{l}{2\exp(K(M+1))}$ to satisfy (3) with l instead of 1 at the right-hand side.

Corollary 4.8 *Let* $d, \varepsilon > 0$, $K \in \mathbb{N}$ *and* $\beta : \mathbb{N} \to \mathbb{N}$ *an arbitrary function. Then there exists an* $n \in \mathbb{N}$ *such that for any normed space* X, *any convex set* $C \subseteq X$ *such that* $d(C) \leq d$, *any nonexpansive function* $f : C \to C$, *any sequence* $\lambda_k \in [0, 1 - \frac{1}{K}]$ *satisfying* $n \leq \sum\limits_{s=0}^{\beta(n)} \lambda_s$ *(for all* $n \in \mathbb{N}$*) and any starting point* $x_0 \in C$ *of the corresponding Krasnoselski-Mann iteration the following holds*

$$\forall m \geq n(\|x_m - f(x_m)\| < \varepsilon).$$

Proof: Follows immediately from corollary 4.6 noticing that if $n \leq \sum\limits_{s=0}^{\beta(n)} \lambda_s$, then also $n \leq \sum\limits_{s=i}^{i+\alpha(i,n)-1} \lambda_s$, where $\alpha(i,n) := \beta(n+i) - i + 1$. But this implies $n \leq \sum\limits_{s=i}^{i+\alpha_+(i,n)-1} \lambda_s$, where $\alpha_+(i,n) := \max\limits_{j \leq i}(\alpha(j,n))$ satisfies $\alpha_+(i,n) \leq \alpha_+(i+1,n)$. $\square$

Remark 4.9 *Using the reasoning from the proof of corollary 4.8 one can rewrite the bounds in theorem 4.5 and corollary 4.6 to depend on* $\beta : \mathbb{N} \to \mathbb{N}$ *satisfying*

$$n \leq \sum_{s=0}^{\beta(n)} \lambda_s$$

instead of α. *We only have to replace* α *by* $\breve{\beta}(i,n) := \max\limits_{j \leq i}(\beta(n+j) - j + 1)$.

Corollary 4.10 *Let* $(X, \|\cdot\|)$, C, f *be as in corollary 4.6,* $k \in \mathbb{N}$, $k \geq 2$ *and* $\lambda_n \in [\frac{1}{k}, 1 - \frac{1}{k}]$ *for all* $n \in \mathbb{N}$. *Consider the Krasnoselski-Mann iteration* $x_{n+1} := (1 - \lambda_n)x_n + \lambda_n f(x_n)$ *starting from* $x_0 := x \in C$. *Then the following holds:*

$$\forall x \in C \forall \varepsilon > 0 \forall n \geq g(\varepsilon, d(C))(\|x_n - f(x_n)\| \leq \varepsilon),$$

where

$$g(\varepsilon, d(C)) := kM \cdot \lceil 2d(C)\exp(k(M+1)) \rceil \; with \; M := \left\lceil \frac{1 + 2d(C)}{\varepsilon} \right\rceil.$$

Proof: We can put in corollary 4.6 $\alpha(i, M) := kM$. One easily proves that $\widehat{\alpha}(i, M) := k(i+1)M$. The corollary now follows from corollary 4.6. $\square$

5 Evaluation of the results of the case study

We have seen that there are interesting proofs in non-linear functional analysis (and specifically in fixed point theory) which fall under general proof theoretic results on the extractability of uniform bounds we had obtained in previous papers.
We applied these results to essentially two proofs

1) A standard proof from [3] (from the year 1962)[19] of the well-known Krasnoselski fixed point theorem.

2) A proof from [4] (which contains as a special case a proof from [11] from 1982) for a general result on the asymptotic behaviour of the Krasnoselski-Mann iteration in arbitrary normed spaces (generalizing a result from Ishikawa [16]).

Results on 1): Logical analysis of a proof from 1955/62 yielded uniform bounds together with an elementary verification for arbitrary bounded convex sets C. Under slightly less general conditions and with the use of the deep Browder-Göhde-Kirk fixed point theorem our bound in theorem 3.9 was obtained only in 1990 ([18]) (The compact case is due already to Krasnoselski). Moreover, a logical modification of the proof using PCM_{ar}^H (with $g(n) = n + 1$ as index function in $\mathrm{PCM}_{ar}^H(a_n)$) allowed to improve this bound under a further condition usually satisfied by moduli of uniform convexity (theorem 3.10). Applying this general bound to L_p ($p \geq 2$) resulted in a polynomial bound of degree p (a result which for this special case was obtained in [18] by an ad hoc calculation). For $X := \mathbb{R}$ and $C := [0, 1]$ we even get a linear bound out of our general result (see also [18], p.192).

Results on 2): Logical analysis of the proof in [4] (resp. [11]) yielded the following results:

For the first time we obtain explicit bounds for Ishikawa's result on the asymptotic behaviour of the general Krasnoselski-Mann iteration in arbitrary normed spaces X and for bounded sets C (corollary 4.6). Moreover, our bounds are uniform in the sense that they only depend on the error ε and an upper bound d_C of the diameter of C (and some data from the sequence of scalars λ_k used in defining the iteration) but not on the nonexpansive function f, the starting point $x_0 \in C$ of the iteration or other C-data. Only the non-effective existence of a bound independent of f and x_0 was known before (see [11] where a non-trivial functional theoretic embedding is used to obtain this uniformity after $\|x_k - f(x_k)\| \to 0$ has been established by the

---

[19]Krasnoselski's original proof from 1955 is very similar to that as far as we can judge from the russian text.

30

proof we are analysing).[20] In fact, [18] explicitly mentions the non-effectivity of all these results and states that 'it seems unlikely that such estimates would be easy to obtain in general setting' (p.191) and therefore only studies the special 'tractable' (p.191) case of uniformly convex spaces due to Krasnoselski. For bounds which, moreover, only depend on C via d_C (corollary 4.8) not even the ineffective existence was known so far and in fact still in [12] (p.101) conjectured as 'unlikely' to be true (incidentally by the same authors whose proof of $\|x_k - f(x_k)\| \to 0$ in [11] does yield such a bound by logical analysis!). Only in the special case of $\lambda_k := \lambda \in (0,1)$ being constant, a uniform (and in fact optimal quadratic) bound was recently discovered using computer aided proofs involving hypergeometric functions (see [1], where again the non-effectivity of all known proofs of the full Ishikawa result is stressed) and only for $\lambda_k := \frac{1}{2}$ a classically proved result of that type has been obtained subsequently (see [2]). This result, of course, is numerically better than our exponential bound in corollary 4.10 when specialised to $\lambda = \frac{1}{2}$. However, as the authors concede, their extremely complicated method does not extend to the case of non-constant sequences (λ_k). [21] Our bound for the general case of unbounded C treated in [4] (theorem 4.5) is apparently all new.

[20]See [9] for a recent interesting application of this uniformity.

[21]Very recently, Kirk ([19]) obtained a new proof of the uniform (w.r.t. x_0 and f) Ishikawa result for the special case $\lambda_k = \lambda$ (again using a functional theoretic embedding) even in the more general setting of so-called directionally nonexansive mappings. It would be interesting to see what quantitative results a logical analysis of that proof would provide. We are grateful to Professor Kirk for bringing the work of Baillon and Bruck to our attention and for communicating to us his recent papers [9],[19].
